## Patents

This product may be protected by U.S. Patent 7,114,180. This list is believed to be current as of May 7, 2012.

## Export Regulation Notice

This product may include cryptographic software. Under the Export Administration Act, the United States government may consider it a criminal offense to export this product from the United States.

## RF Interference Warning

This is a Class A product. In a domestic environment this product may cause radio interference, in which case the user may be required to take adequate measures.

## Legal Notices

### **FCC Compliance**

This equipment has been tested and found to comply with the limits for a Class A digital device pursuant to Part 15 of FCC rules. These limits are designed to provide reasonable protection against harmful interference when the equipment is operated in a commercial environment. This unit generates, uses, and can radiate radio frequency energy and, if not installed and used in accordance with the instruction manual, may cause harmful interference to radio communications. Operation of this equipment in a residential area is likely to cause harmful interference, in which case the user, at his own expense, will be required to take whatever measures may be required to correct the interference.

Any modifications to this device, unless expressly approved by the manufacturer, can void the user's authority to operate this equipment under part 15 of the FCC rules.

### **Canadian Regulatory Compliance**

This Class A digital apparatus complies with Canadian ICES-003.

### **Standards Compliance**

This product conforms to the IEC, European Union, ANSI/UL and Canadian CSA standards applicable to Information Technology products at the time of manufacture.

# Chapter 1

---

## About Network Access

---

### Topics:

- *What is network access?*
  - *Network access features*
  - *About network access traffic*
  - *Network access configuration elements*
-

## What is network access?

---

The BIG-IP® Access Policy Manager® network access feature provides secure access to corporate applications and data using a standard web browser, or the BIG-IP Edge Client®. Using network access, employees, partners, and customers can have access to corporate resources securely, from any location.

The network access feature provides users with the functionality of a traditional IPsec VPN client. Unlike IPsec, however, network access does not require any pre-installed software or configuration on the remote user's computer. It is also more robust than IPsec VPN against router and firewall incompatibilities.

## Network access features

---

Network access provides connections with the following features.

<b>Full access from any client</b>	Provides Windows®, Macintosh®, Linux®, and Windows Mobile users with access to the complete set of IP-based applications, network resources, and intranet files available, as if they were physically working on the office network.
<b>Split tunneling of traffic</b>	Provides control over exactly what traffic is sent over the network access connection to the internal network, and what is not. This feature provides better client application performance by allowing connections to the public Internet to go directly to their destinations, rather than being routed over the tunnel and then out to the public Internet.
<b>Client checking</b>	Detects operating system and browser versions, antivirus and firewall software, registry settings, and processes, and checks files during the login process to insure that the client configuration meets the organization's security policy for remote access.
<b>Compression of transferred data</b>	Compresses traffic with GZIP before it is encrypted, reducing the number of bytes transferred between the Access Policy Manager and the client system and improving performance.
<b>Routing table monitoring</b>	Monitors changes made in the client's IP routing table during a network access connection. You can configure this feature to stop the connection if the routing table changes, helping prevent possible information leaks. This feature applies to Windows clients only.
<b>Session inactivity detection</b>	Closes network access connections after a period below an inactivity threshold that you can configure. This feature helps prevent security breaches.
<b>Automatic application start</b>	Starts a client application automatically after establishing the network access connection. This feature simplifies user access to specific applications or sites.
<b>Automatic drive mapping</b>	Connects the user to a specific drive on the intranet. This feature simplifies user access to files.

*Note: This feature is available only for Windows clients.*

---

<b>Connection-based ACLs</b>	Filters network traffic by controlling whether packets are allowed, discarded, or rejected, based on specific criteria. For example, connections can be filtered
------------------------------	--

by Layer 4 properties like source and destination IP address and port, protocol (TCP or UDP), and Layer 7 properties like scheme, host name, and paths. ACLs also support auditing capabilities with logging. ACLs allow groups of users or access policy users to have access to full client-server application support without opening up the entire network to each user.

**Dynamic IP address assignment**

Assigns client endpoint IP addresses dynamically from a configured pool of addresses. IP addresses can also be assigned with an external AAA server attribute.

**Traffic classification, prioritization, and marking**

Provides the ability to classify and prioritize traffic to ensure levels of service to users with defined characteristics.

## About network access traffic

---

Network access implements a point-to-point network connection over SSL, which provides a secure solution that works well with firewalls and proxy servers.

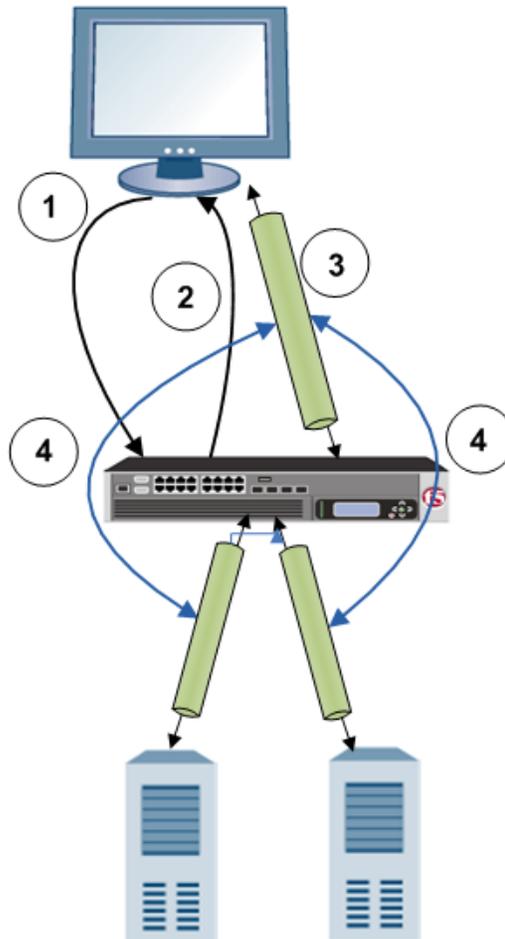

Network access settings specify IP address pools, which the Access Policy Manager® then uses to assign IP addresses to a client computer's virtual network adapter. When an end user opens the address of the Access Policy Manager in a web browser, the browser starts an SSL connection to the Access Policy Manager. The user can then log in to the Access Policy Manager.

## Network access connection diagram

The process flow of a network access connection is depicted in this diagram.

## About Network Access

- 1 The user starts a 443 SSL session with the Access Policy Manager, and logs on.
- 2 The Access Policy Manager downloads and installs the ActiveX control or browser plugin to the client.
- 3 The ActiveX control or browser plugin establishes an encrypted network access tunnel with the Access Policy Manager.
- 4 The user connects to internal servers over the Network Access connection, as if the client is located directly on the internal network.

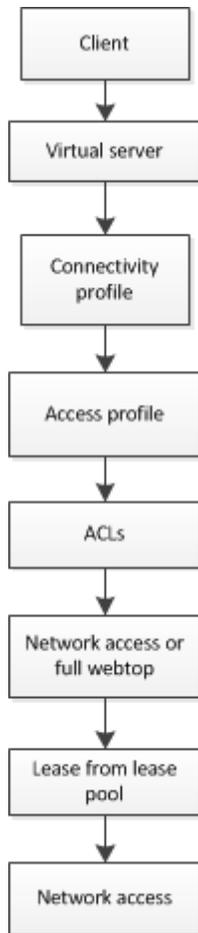

## Network access configuration elements

---

A network access configuration requires:

- A network access resource
- An access profile, with an access policy that assigns:
  - A network access resource
  - A network access or full webtop
- A lease pool that provides internal network addresses for tunnel clients
- A connectivity profile
- A virtual server that assigns the access profile

Network access elements are summarized in the following diagram.

**Figure 1: Network access elements**

## About Network Access

---

# Chapter 2

---

## Configuring Network Access Resources

---

### Topics:

- *Creating a network access resource*
- *Configuring properties for a network access resource*
- *Configuring network settings for a network access resource*
- *Configuring DNS and hosts for a network access resource*
- *Mapping drives for a network access resource*
- *Launching applications on a network access connection*

### Creating a network access resource

---

You configure a network access resource to allow users access to your local network through a secure VPN tunnel.

1. On the Main tab, click **Access Policy > Network Access**.  
The Network Access List screen opens.
2. Click the **Create** button.  
The New Resource screen opens.
3. In the **Name** field, type a name for the resource.
4. Type an optional description for the network access resource.
5. Click **Finished** to save the network access resource.

The General Properties screen for the network access resource opens.

You can configure the properties for the network access resource using the menu bar at the top of the screen. Later, you assign the network access resource to an access policy using one of the resource assign actions.

### Configuring properties for a network access resource

---

You must create a network access resource, or open an existing resource, before you can perform this task.

You can configure the description of a network access resource with network access properties.

1. On the Main tab, click **Access Policy > Network Access**.  
The Network Access Resource List screen opens.
2. Click the name to select a network access resource on the Resource List.  
The Network Access editing screen opens.
3. To configure the general properties for the network resource, click **Properties** on the menu bar.
4. Click the **Update** button.  
Your changes are saved and the page refreshes.

### Network access resource properties

Use General Properties to update settings for the network access resource.

Setting	Value	Description
Name	A text string. Avoid using global reserved words in the name, such as all, delete, disable, enable, help, list, none, or show.	The name for the network access resource.
Partition	Typically, <b>common</b> .	The partition under which the network access resource is created. You cannot change this value.
Description	A text description of the network access resource.	The description appears in the client as a name for the network access resource.

## Configuring network settings for a network access resource

You must create a network access resource, or open an existing resource, before you can perform this task.

You can use network settings to specify a lease pool for network access clients, and also to configure traffic options, client behavior, DTLS settings, and set up proxy behavior.

1. On the Main tab, click **Access Policy > Network Access**.  
The Network Access List screen opens.
2. Click the name to select a network access resource on the Resource List.  
The Network Access editing screen opens.
3. To configure the network settings for the network access resource, click **Network Settings** on the menu bar.
4. Click the **Update** button.  
Your changes are saved and the page refreshes.

### Proxy ARP considerations

To configure proxy ARP, you must be aware of the following conditions.

- Proxy ARP is not compatible with SNAT pools. You must disable SNAT Automap or a specific SNAT pool to use proxy ARP.
- If you enable split tunneling, you must configure an entry for the server LAN segment in the **LAN Address Space** setting. You must also configure the LAN address spaces for any clients that will send traffic to each other.
- In a high availability configuration, both BIG-IP® systems must have interfaces on the same server LAN segment.
- IP addresses that you reserve for tunnel clients cannot be used for self IPs, NATs, SNATs, or wildcard (port-0) virtual servers.

### Network settings for a network access resource

Network settings specify tunnel settings, session settings, and client settings.

Setting	Value	Description
<b>Network Tunnel</b>	Enable	When you enable a network tunnel, you configure the network access tunnel to provide network access. Clear the <b>Enable</b> option to hide all network settings and to disable the tunnel.
<b>Supported IP Version</b>	<b>IPv4</b> or <b>IPv4&amp;IPv6</b>	<p>Sets the Network Access tunnel to support either an IPv4 lease pool, or both IPv4 and IPv6 lease pools.</p> <p> <b>Important:</b> Network access with IPv6 alone is not supported. An IPv6 tunnel requires a simultaneous IPv4 tunnel, which is automatically established when you assign IPv4 and IPv6 lease pools, and set the version to <b>IPv4&amp;IPv6</b>.</p>

## Configuring Network Access Resources

Setting	Value	Description
<b>General Settings</b>	Basic/Advanced	Select <b>Advanced</b> to show settings for Proxy ARP, SNAT Pool, and Session Update.
<b>IPv4 Lease Pool</b>	List selection of existing IPv4 lease pools	Assigns internal IP addresses to remote network access clients, using configured lease pools. Select a lease pool from the drop-down list. To create a lease pool within this screen, click the + sign next to <b>Lease Pool</b> .
<b>IPv6 Lease Pool</b>	List selection of existing IPv6 lease pools	Assigns internal IP addresses to remote network access clients, using configured lease pools. Select a lease pool from the drop-down list. To create a lease pool within this screen, click the + sign next to <b>Lease Pool</b> .
<b>Compression</b>	<b>No Compression/GZIP Compression</b>	Select GZIP Compression to compress all traffic between the Network Access client and the Access Policy Manager <sup>®</sup> , using the GZIP deflate method.
<b>Proxy ARP</b>	Enable	Proxy ARP allows remote clients to use IP addresses from the LAN IP subnet, and no configuration changes are required on other devices such as routers, hosts, or firewalls. IP address ranges on the LAN subnet are configured in a lease pool and assigned to network access tunnel clients. When this setting is enabled, a host on the LAN that sends an ARP query for a client address gets a response from Access Policy Manager with its own MAC address. Traffic is sent to the Access Policy Manager and forwarded to clients over network access tunnels.
<b>SNAT Pool</b>	List selection of <b>None, Auto Map,</b> or SNAT pool name	Specifies the name of a SNAT pool used for implementing selective and intelligent SNATs. The default is <b>Auto Map</b> . If you have defined a SNAT on the system, that SNAT is available as an option on this list. The following two options are always available. <ul style="list-style-type: none"> <li>• <b>None</b> specifies that the system uses no SNAT pool for this network resource.</li> <li>• <b>Auto Map</b> specifies that the system uses all of the self IP addresses as the translation addresses for the pool.</li> </ul>
<b>Session Update Threshold</b>	Integer (bytes per second)	Defines the average byte rate that either ingress or egress tunnel traffic must exceed, in order for the tunnel to update a session. If the average byte rate falls below the specified threshold, the system applies the inactivity timeout, which is defined in the Access Profile, to the session.
<b>Session Update Window</b>	Integer (seconds)	Defines the time value in seconds that the system uses to calculate the EMA (Exponential Moving Average) byte rate of ingress and egress tunnel traffic.
Client Settings	Basic/Advanced	Select <b>Advanced</b> to configure client proxy, DTLS, domain reconnect settings, and client certificate options.
<b>Force all traffic through tunnel</b>	Enable/disable	Specifies that all traffic (including traffic to or from the local subnet) is forced over the VPN tunnel.

<b>Setting</b>	<b>Value</b>	<b>Description</b>
<b>Use split tunneling for traffic</b>	Enable/disable	Specifies that only the traffic targeted to a specified address space is sent over the network access tunnel. With split tunneling, all other traffic bypasses the tunnel. By default, split tunneling is not enabled. When split tunneling is enabled, all traffic passing over the network access connection uses this setting.
<b>IPV4 LAN Address Space</b>	IPv4 IP address, IP address and network mask	Provides a list of addresses or address/mask pairs describing the target LAN. When using split tunneling, only the traffic to these addresses and network segments goes through the tunnel configured for Network Access. You can add multiple address spaces to the list, one at a time. For each address space, type the IP address and the network mask and click <b>Add</b> .
<b>IPV6 LAN Address Space</b>	IPv6 IP address, IP address and network mask	Provides a list of IPv6 addresses or address/mask pairs describing the target LAN. When using split tunneling, only the traffic to these addresses and network segments goes through the tunnel configured for Network Access. You can add multiple address spaces to the list, one at a time. For each address space, type the IP address and the network mask and click <b>Add</b> . This list appears only when you select <b>IPV4&amp;IPV6</b> in the <b>Supported IP Version</b> setting.
<b>DNS Address Space</b>	domain names, with or without wildcards	Provides a list of domain names describing the target LAN DNS addresses. This field only appears if you use split tunneling. You can add multiple address spaces to the list, one at a time. For each address space, type the domain name, in the form <code>site.siterequest.com</code> or <code>*.siterequest.com</code> , and click <b>Add</b> .
<b>Exclude Address Space</b>	IP address/network mask pairs	Specifies address spaces whose traffic is not forced through the tunnel. For each address space that you want to exclude, type the IP address and the network mask and click <b>Add</b> .
<b>Allow Local Subnet</b>	Enable/disable	Select this option to enable local subnet access and local access to any host or subnet in routes that you have specified in the client routing table. When you enable this setting, the system does not support integrated IP filtering.
Client Side Security > <b>Prohibit routing table changes during Network Access connection</b>	Enable/disable	This option closes the network access session if the client's IP routing table is modified during the session.
Client Side Security > <b>Integrated IP filtering engine</b>	Enable/disable	Select this option to protect the resource from outside traffic (traffic generated by network devices on the client's LAN), and to ensure that the resource is not leaking traffic to the client's LAN.
Client Side Security > <b>Allow access to local DHCP server</b>	Enable/disable	This option appears when the <b>Integrated IP filtering engine</b> option is enabled. This option allows the client access to connect through the IP filtering engine, to use a DHCP server local to the client to renew the client DHCP lease locally.

## Configuring Network Access Resources

Setting	Value	Description
		<p>This option is not required or available when IP filtering is not enabled, because clients can renew their leases locally.</p> <hr/> <p> <b>Important:</b> This option does not renew the DHCP lease for the IP address assigned from the network access lease pool; this applies only to the local client IP address.</p> <hr/>
<b>Client Traffic Classifier</b>	List selection	Specifies a client traffic classifier to use with this network access tunnel, for Windows clients.
Client Options > <b>Client for Microsoft Networks</b>	Enable/disable	Select this option to allow the client PC to access remote resources over a VPN connection. This option is enabled by default. This allows the VPN to work like a traditional VPN, so a user can access files and printers from the remote Microsoft network.
Client Options > <b>File and printer sharing for Microsoft networks</b>	Enable/disable	Select this option to allow remote hosts to access shared resources on the client computer over the network access connection. This allows the VPN to work in reverse, and a VPN user to share file shares and printers with remote LAN users and other VPN users.
<b>Provide client certificate on Network Access connection when requested</b>	Enable/disable	If client certificates are required to establish an SSL connection, this option must always be enabled. However, you can disable this option if the client certificates are only requested in an SSL connection. In this case, the client is configured not to send client certificates.
Reconnect to Domain > <b>Synchronize with Active Directory policies on connection establishment</b>	Enable/disable	<p>When enabled, this option emulates the Windows logon process for a client on an Active Directory domain. Network policies are synchronized when the connection is established, or at logoff. The following items are synchronized:</p> <ul style="list-style-type: none"> <li>• Logon scripts are started as specified in the user profile.</li> <li>• Drives are mapped as specified in the user profile.</li> <li>• Group policies are synchronized as specified in the user profile. Group Policy logon scripts are started when the connection is established, and Group Policy logoff scripts are run when the network access connection is stopped.</li> </ul>
Reconnect to Domain > <b>Run logoff scripts on connection termination</b>	Enable/disable	This option appears when <b>Synchronize with Active Directory policies on connection establishment</b> is enabled. Enable this option if you want the system to run logoff scripts, as configured on the Active Directory domain, when the connection is stopped.
<b>Client Interface Speed</b>	Integer, bits per second	Specifies the maximum speed of the client interface connection, in bits per second.
<b>Display connection tray icon</b>	Enable/disable	When enabled, balloon notifications for the network access tray icon (for example, when a connection is made) are displayed. Disable this option to prevent balloon notifications.

<b>Setting</b>	<b>Value</b>	<b>Description</b>
<b>Client Power Management</b>	<b>Ignore, Prevent, or Terminate</b>	Specifies how network access handles client power management settings, for example, when the user puts the system in standby, or closes the lid on a laptop. <ul style="list-style-type: none"> <li>• <b>Ignore</b> - ignores the client settings for power management.</li> <li>• <b>Prevent</b> - prevents power management events from occurring when the client is enabled.</li> <li>• <b>Terminate</b> - terminates the client when a power management event occurs.</li> </ul>
<b>DTLS</b>	Enable/disable	Specifies, when enabled, that the network access connection uses Datagram Transport Level Security (DTLS). DTLS uses UDP instead of TCP, to provides better throughput for high-demand applications like VoIP or streaming video, especially with lossy connections.
<b>DTLS Port</b>	Port number	Specifies the port number that the network access resource uses for secure UDP traffic with DTLS. The default is 4433.
<b>Client Proxy Settings</b>	Enable/disable	When selected, provides configuration settings for client proxy connections for this network access resource.
<b>Client Proxy Uses HTTP for Proxy Autoconfig Script</b>	Enable/disable	Some applications, like Citrix® MetaFrame, can not use the client proxy autoconfig script when the browser attempts to use the <code>file://</code> prefix to locate it. Select this option to specify that the browser uses <code>http://</code> to locate the proxy autoconfig file, instead of <code>file://</code> .
<b>Client Proxy Autoconfig Script</b>	URL	The URL for a proxy auto-configuration script, if one is used with this connection.
<b>Client Proxy Address</b>	IP address	The IP address for the client proxy server that network access clients use to connect to the Internet.
<b>Client Proxy Port</b>	Port number	The port number of the proxy server that network access clients use to connect to the Internet.
<b>Bypass Proxy For Local Addresses</b>	Enable/disable	Select this option if you want to allow local intranet addresses to bypass the proxy server.
<b>Client Proxy Exclusion List</b>	IP addresses, domain names, with wildcards	Specifies the web addresses that do not need to be accessed through your proxy server. You can use wildcards to match domain and host names, or addresses. For example, <code>www.*.com</code> , <code>128.*</code> , <code>240.8.8.</code> , <code>mygroup.*</code> , <code>*.*</code> .

## **Configuring DNS and hosts for a network access resource**

You must create a network access resource, or open an existing resource, before you can perform this task.

You can configure DNS and hosts to configure how a user's tunnel connection resolves addresses.

1. On the Main tab, click **Access Policy > Network Access**.  
The Network Access List screen opens.

## Configuring Network Access Resources

2. Click the name to select a network access resource on the Resource List.  
The Network Access editing screen opens.
3. To configure DNS and hosts settings for the network access resource, click **DNS/Hosts** on the menu bar.
4. Configure DNS and Hosts settings as required.
5. Click the **Update** button.  
Your changes are saved and the page refreshes.

### Network access resource DNS and hosts settings

DNS and hosts settings specify lookup information for remote tunnel clients.

Setting	Value	Description
Primary Name Server	IP address	Type the IP address of the DNS server that network access conveys to the remote access point.
Secondary Name Server	IP address	Type a second IP address for the DNS server that network access conveys to the remote access point.
Primary WINS Server	IP address	Type the IP address of the WINS server in order to communicate to the remote access point. This address is needed for Microsoft Networking to function properly.
Secondary WINS Server	IP address	Type the IP address of the WINS server to be conveyed to the remote access point. This address is needed for Microsoft networking to function properly.
DNS Default Domain Suffix	domain suffix	Type a DNS suffix to send to the client. If this field is left blank, the controller will send its own DNS suffix. For example, <code>siterequest.com</code> .   <b>Tip:</b> You can specify multiple default domain suffixes separated with commas.
Static Hosts	host name/IP address pairs	To add host and IP addresses manually to a connection-specific hosts file, type the <b>Host Name</b> and the <b>IP Address</b> for that host in the provided fields, and click <b>Add</b> .

### Mapping drives for a network access resource

You must create a network access resource, or open an existing resource, before you can perform this task.

Use drive mappings to map network locations to drive letters on Windows®-based client systems.

1. On the Main tab, click **Access Policy > Network Access**.  
The Network Access List screen opens.
2. Click the name to select a network access resource on the Resource List.  
The Network Access editing screen opens.
3. To configure the drive mappings for the network access resource, click **Drive Mappings** on the menu bar.

4. Click **Add** to add a new drive mapping.
5. Type the **Path**, select the **Drive** letter, and type an optional **Description** for the drive mapping.
6. Click **Finished**.  
The drive mapping is added to the network access resource.

## Network access resource drive mapping settings

In the short description, briefly describe the purpose and intent of the information contained in this topic.

Setting	Value	Description
Path	A network path, for example \\networkdrive\users	Specifies the path to the server network location.
Drive	Drive letter, list selection	Specifies the drive used. <b>Drive</b> is set to D: by default. Drive mapping is supported for Windows clients only.
Description	Text	An optional description of the drive mapping.

## Launching applications on a network access connection

You must create a network access resource, or open an existing resource, before you can perform this task.

Use application launching to start applications on network access clients after the tunnel is established.

1. On the Main tab, click **Access Policy > Network Access**.  
The Network Access List screen opens.
2. Click the name to select a network access resource on the Resource List.  
The Network Access editing screen opens.
3. To configure applications to start for clients that establish a network access connection with this resource, click **Launch Applications** on the menu bar.
4. Click **Add** to add a new application.
5. Type the **Application Path**, type any required **Parameters** letter, and select the **Operating System**.
6. Click **Finished**.  
The application start configuration is added to the Launch Applications list, and the applications appropriate to the client operating system start when a client establishes a tunnel connection.

## Network access launch applications settings

Specify launch application settings to control how applications are launched when the network access connection starts.

Setting	Value	Description
Display warning before launching applications	Enable or disable	If you enable this setting, the system displays security warnings before starting applications from network access, regardless of whether the site is considered a Trusted site. If the check box is not

## Configuring Network Access Resources

Setting	Value	Description
		selected, the system displays security warnings if the site is not in the Trusted Sites list.
Application Path	An application path	Specifies the path to the application. You can type special application paths here: <ul style="list-style-type: none"><li>• <code>reconnect_to_domain</code> - Type this application path to specify that the client reconnects to the domain after the network access tunnel starts. Use this if, for example, the network access tunnel is established before the domain controller logon occurs.</li><li>• <code>/gpo_logoff_scripts</code> - Type this in the application path field to run group policy object (GPO) logoff scripts on the client when the network access tunnel is stopped.</li></ul>
Parameters	Text	Parameters that govern the application launch.
Operating System	List selection	From the list, select whether the application launch configuration applies to Windows-based, Unix-based, Macintosh-based, or iOS clients.

---

# Chapter 3

---

## Creating Optimized Application Tunnels

---

Topics:

- *What is an optimized application?*
-

### What is an optimized application?

---

An *optimized application* is a set of compression characteristics that are applied to traffic flowing from the network access client to a specific IP address, network, or host, on a specified port or range of ports. An optimized tunnel provides a TCP Layer 4 connection to an application. You can configure optimized applications separately from the standard TCP Layer 3 network access tunnel specified on the **Network Settings** page.

Optimized application tunnels take precedence over standard network access tunnels, so for specified destinations, an optimized connection is established, whether the network access tunnel is enabled or not. In cases where optimized application tunnels have overlapping addresses or ranges, tunnels are prioritized in the following order:

- An address definition with a more specific network mask takes precedence.
- An address definition with a scope defined by a more specific subnet takes precedence.
- A tunnel defined by a host name takes precedence over a tunnel defined by an IP address.
- A tunnel defined by a host name takes precedence over a tunnel defined by a host name with a wildcard. For example, `web.siterequest.com` takes precedence over `*.siterequest.com`.
- A tunnel defined by a host name with a wildcard takes precedence over a tunnel defined by a network address. For example, `*.siterequest.com` takes precedence over `1.2.3.4/16`.
- For equivalent tunnels with different port ranges, the tunnel with a smaller port range takes precedence. For example, `web.siterequest.com:21-22` takes precedence over `web.siterequest.com:21-30`.

### Configuring an optimized application on a network access tunnel

You must create a network access resource, or open an existing resource, before you can perform this task.

You can configure the description of a network access resource with network access properties.

1. On the Main tab, click **Access Policy > Network Access**.  
The Network Access List screen opens.
2. Click the name to select a network access resource on the Resource List.  
The Network Access editing screen opens.
3. To configure optimization for a host with the network access resource, click **Optimization** on the menu bar.
4. Click **Add** to add a new optimized application configuration.
5. Configure the destination and port settings, and any required optimization characteristics.
6. Click **Finished**.  
The optimized application configuration is added to the network access resource.
7. Click the **Update** button.  
Your changes are saved and the page refreshes.

### Optimized application settings

Use the following settings to configure an optimized application.

<b>Setting</b>	<b>Value</b>	<b>Description</b>
Optimized Application	Basic/Advanced	Select <b>Basic</b> to show only destination and port settings, and <b>Advanced</b> to show optimization settings for the application destination.
Destination Type: Host Name	Fully qualified domain name (FQDN)	Select this option to apply optimization to a specific named host. Specify a fully qualified domain name (FQDN) for the destination.
Destination Type: IP Address	IP Address	Select this option to apply optimization to a host at a specific IP address. Specify an IP address for the destination. This can be an IPv4 or IPv6 address.
Destination Network	Network IP address and network mask	Select this option to apply optimization to a network. Specify a network IP address and subnet mask for the destination. This can be an IPv4 or IPv6 address.
Port(s)	Specific numeric port, list selection, or port range	You can specify a single port on which to optimize traffic, or select <b>Port Range</b> to specify an inclusive range. If you optimize traffic on a single port, you can type a port number, or you can select an application from the list of common applications to add the appropriate port, for example, FTP.
Deflate	Enabled/Disabled	Enable or disable Deflate compression. Deflate compression uses the least CPU resources, but compresses the least effectively.
LZO	Enabled/Disabled	Enable or disable LZO compression. LZO compression offers a balance between CPU resources and compression ratio, compressing more than Deflate compression, but with less CPU resources than Bzip2.
Bzip2	Enabled/Disabled	Enable or disable bzip2 compression. Bzip2 compression uses the most CPU resources, but compresses the most effectively.

## Creating Optimized Application Tunnels

---

# Chapter 4

---

## Configuring Lease Pools

---

Topics:

- [What is a lease pool?](#)
-

### What is a lease pool?

---

A *lease pool* specifies a group of IPv4 or IPv6 IP addresses as a single object. You can use a lease pool to associate that group of IP addresses with a network access resource. When you assign a lease pool to a network access resource, network access clients are automatically assigned unallocated IP addresses from the pool during the network access session.

**Important:** Network access with IPv6 alone is not supported. An IPv6 tunnel requires a simultaneous IPv4 tunnel, which is automatically established when you assign IPv4 and IPv6 lease pools, and set the version to **IPv4&IPv6**.

---

### Creating an IPv4 lease pool

Create a lease pool to provide internal network addresses for network access tunnel users.

1. On the Main tab, select **Access Policy > Network Access > Lease Pools > IPv4 Lease Pools**. The IPv4 Lease Pools list appears.
2. Click the **Create** button.
3. In the **Name** field, type a name for the resource.
4. Add IPv4 addresses to the lease pool.
  - To add a single IP address, in the Member List area, select **IP Address** for the type. In the **IP Address** field, type the IP address.
  - To add a range of IP addresses, in the Member List area, select **IP Address Range** for the type. In the **Start IP Address** field, type the first IP address, and in the **End IP Address** field, type the last IP address.
5. Click the **Add** button.

A lease pool is created with the IP address or IP address range you specified.

To delete an IP address or IP address range, select the IP address or IP address range in the member list, and click the **Delete** button.

### Creating an IPv6 lease pool

Create a lease pool to provide internal network addresses for network access tunnel users.

**Important:** Network access with IPv6 alone is not supported. An IPv6 tunnel requires a simultaneous IPv4 tunnel, which is automatically established when you assign IPv4 and IPv6 lease pools, and set the version to **IPv4&IPv6**.

---

1. On the Main tab, select **Access Policy > Network Access > Lease Pools > IPv6 Lease Pools**. The IPv6 Lease Pools list appears.
2. Click the **Create** button.
3. In the **Name** field, type a name for the resource.
4. Add IPv6 addresses to the lease pool.

- To add a single IP address, in the Member List area, select **IP Address** for the type. In the **IP Address** field, type the IP address.
- To add a range of IP addresses, in the Member List area, select **IP Address Range** for the type. In the **Start IP Address** field, type the first IP address, and in the **End IP Address** field, type the last IP address.

5. Click the **Add** button.

A lease pool is created with the IP address or IP address range you specified.

To delete an IP address or IP address range, select the IP address or IP address range in the member list, and click the **Delete** button.

## Configuring Lease Pools

---

# Chapter 5

---

## Shaping Traffic on the Network Access Client

---

**Topics:**

- *About Windows client traffic shaping*
  - *Configuring client traffic shaping*
-

### About Windows client traffic shaping

---

Used together, client traffic classifiers and client rate classes provide client-side traffic shaping features on Windows® network access client connections. You configure a *client traffic classifier*, which defines source and destination IP addresses or networks, and can also specify a protocol. The client traffic classifier is then associated with a *client rate class*, which defines base and peak rates for traffic to which it applies, and other traffic shaping features. A client traffic classifier is assigned in a network access resource.

**Important:** *Client traffic classifiers support IPv4 addresses only.*

---

### Configuring client traffic shaping

---

Client rate shaping allows you to shape client-side traffic from Windows® client systems, based on traffic parameters.

1. Create a client rate class.
2. Create a client traffic classifier.

When you create the client traffic classifier, you select the previously created client rate class.

Together, the client rate class and client traffic classifier work to provide client-side traffic control to Windows clients to which the traffic control is applied.

Select the client traffic classifier in the **Network Settings** configuration of a network access resource. The client traffic classifier is then applied to Windows clients, for client-side traffic on the VPN tunnels defined by that network access resource.

### Creating a client rate class

Create a client rate class to define the traffic shaping rules that you can apply to virtual and physical interfaces on a network access tunnel.

1. On the Main tab, click **Access Policy > Network Access > Client Traffic Control > Client Rate Classes**.
2. Click **Create**.  
The New Client Rate Class screen opens.
3. In the **Name** field, type the name for the new client rate class.
4. Select **Basic** or **Advanced**.  
The Advanced configuration allows you to configure the burst size, the rate class mode, and override the DSCP code.
5. In the **Base Rate** field, type the base rate for the client rate class. Select the units for the peak rate from the list (**bps**, **Kbps**, **Mbps**, or **Gbps**).
6. In the **Ceiling Rate** field, type the peak rate for the client rate class. Select the units for the ceiling rate from the list (**bps**, **Kbps**, **Mbps**, or **Gbps**).

7. In the **Burst Size** field, type the amount of traffic that is allowed to reach the ceiling rate defined for the traffic rate class. You can select the units for this number from the list (**bytes, Kilobytes, Megabytes, or Gigabytes**).
8. From the **Service Type** list, select the service type.
9. From the **Mode** list, select the traffic shaping mode.
10. (Optional) If you are using a differential services network, you can specify the DSCP value with which to mark this traffic by selecting the **DSCP Override** check box.  
In the field, type the number of the DSCP code with which to mark traffic.
11. Click **Finished**.

The client rate class is created.

Select this client rate class in a client traffic classifier to apply it to Windows® client-side traffic.

### Client rate class properties

Client rate class properties specify settings for client traffic control rates.

Setting	Value	Description
<b>Base Rate</b>	Integer in <b>bps, Kbps, Mbps, or Gbps</b>	Specifies the base data rate defined for the client rate class.
<b>Ceiling Rate</b>	Integer in <b>bps, Kbps, Mbps, or Gbps</b>	Specifies the ceiling data rate defined for the client rate class.
<b>Burst Size</b>	Integer in <b>bytes, Kilobytes, Megabytes, or Gigabytes</b>	Specifies the amount of traffic that is allowed to reach the ceiling data rate defined for the client rate class.
<b>Service Type</b>	<b>Best Effort, Controlled Load, or Guaranteed</b>	<ul style="list-style-type: none"> <li>• <b>Best Effort</b> - Specifies that Windows® traffic control creates a flow for this client traffic class, and traffic on the flow is handled with the same priority as other Best Effort traffic.</li> <li>• <b>Controlled Load</b> - Specifies that traffic control transmits a very high percentage of packets for this client rate class to its intended receivers. Packet loss for this service type closely approximates the basic packet error rate of the transmission medium. Transmission delay for a very high percentage of the delivered packets does not greatly exceed the minimum transit delay experienced by any successfully delivered packet.</li> <li>• <b>Guaranteed</b> - Guarantees that datagrams arrive within the guaranteed delivery time and are not discarded due to queue overflows, provided the flow's traffic stays within its specified traffic parameters. This service type is intended for applications that require guaranteed packet delivery.</li> </ul>
<b>Mode</b>	<b>Shape, Discard, or Borrow</b>	<ul style="list-style-type: none"> <li>• <b>Shape</b> - Delays packets submitted for transmission until they conform to the specified traffic profile.</li> <li>• <b>Discard</b> - Discards packets that do not conform to the specified traffic control profile.</li> <li>• <b>Borrow</b> - Allows traffic on the client rate class to borrow resources from other flows that are temporarily idle. Traffic that borrows resources is marked as nonconforming, and receives a lower priority.</li> </ul>

## Shaping Traffic on the Network Access Client

Setting	Value	Description
<b>DSCP</b>	Enable/disable, integer for DSCP code	If you select <b>Override</b> , you can specify an optional DSCP code for the client rate class. DSCP is a way of classifying traffic for Quality of Service (QoS). Traffic is classified using six-bit values, and then routers on the network interpret the traffic priority based on their configurations and prioritize traffic for QoS accordingly.

### Creating a client traffic classifier

You must create at least one client rate class before you create a client traffic classifier. You select client rate classes to define rules in the client traffic classifier.

Create a client traffic classifier to define traffic control rules for the virtual and physical network interfaces on a network access tunnel.

1. On the **Main** tab, click **Access Policy > Network Access > Client Traffic Control > Client Traffic Classifiers**.
2. Click **Create**.  
The New client rate class screen opens.
3. In the **Name** box, type a name for the client traffic classifier, and click **Create**.  
The Client Traffic Classifiers list screen opens.
4. Click the name of the client traffic classifier you just created.
5. Add rules for the appropriate interface.

Rule type	Description
<b>Rules for Virtual Network Access Interface</b>	Add a rule to this section to apply the traffic shaping control only to traffic on the virtual network access interface.
<b>Rules for Local Physical Interfaces</b>	Add a rule to this section to apply the traffic shaping control only to traffic on the client computer's local physical interfaces.
<b>Rules for Virtual Network Access and Local Physical Interfaces</b>	Add a rule to this section to apply the traffic shaping control to traffic on both the virtual Network Access interface and the client's local physical interfaces.

### Adding a client traffic classifier entry

You add entries to an existing client traffic classifier. You must first create a client traffic classifier, and at least one client rate class.

Client traffic classifiers define client traffic control for virtual and physical network interfaces on the client systems.

1. On the **Main** tab, click **Access Policy > Network Access > Client Traffic Control > Client Traffic Classifiers**.
2. Click the name of a client traffic classifier.
3. Under the appropriate interface **Rules** area, click **Add**.  
The New Client Traffic Classifier Entry screen opens.
4. Select **Basic** or **Advanced**.

**Advanced** mode allows you to configure a source address and source ports for the client traffic control entry.

5. Select a **Client Rate Class** entry.
6. Specify any settings you require for the client traffic classifier entry.  
Note that currently you can only specify an IPv4 address for a client traffic classifier host entry.
7. When you have finished configuring the client traffic classifier entry, click **Finished**.  
The configuration screen for the client traffic classifier appears again.

The client traffic classifier is updated with the client traffic classifier entry in the **Rules** area you specified.

**Client traffic classifier entry properties**

Configure properties for the client traffic classifier to determine how traffic is classified for traffic shaping on Windows® clients.

<b>Property</b>	<b>Values</b>	<b>Description</b>
Basic/Advanced	Basic or Advanced (list item)	<b>Advanced</b> allows you to configure a source address and source ports.
Client Rate Class	List item	A client rate class defines the client traffic shaping rates and properties for a client traffic control configuration. Because client traffic classifier entries define address pairs and protocols on which client rate classes operate, a client rate class must be created before you can use a client traffic classifier entry.
Protocol	UDP, TCP, or All Protocols.	The protocol to which this client traffic classifier entry applies.
Destination Address	Selection and manual entries	The destination address to which the client traffic classifier entry applies. <ul style="list-style-type: none"> <li>• <b>Any</b> applies the client traffic classifier entry to any destination address.</li> <li>• <b>Host</b> applies the client traffic classifier entry to a specific host IP address. Type the IP address in the box that appears.</li> <li>• <b>Network</b> applies the client traffic classifier entry to a network address. Type the network address and the network mask in the boxes that appear.</li> </ul>
Destination Port	Number or list item	The destination port to which the client traffic classifier entry applies. You can type the port number, or select from the list of predefined application ports.
Source Address	Selection and manual entries	The source address to which the client traffic classifier entry applies. <ul style="list-style-type: none"> <li>• <b>Any</b> applies the client traffic classifier entry to any source address.</li> <li>• <b>Host</b> applies the client traffic classifier entry to a specific host IP address. Type the IP address in the box that appears.</li> <li>• <b>Network</b> applies the client traffic classifier entry to a network address. Type the network address and the network mask in the boxes that appear.</li> </ul>

## Shaping Traffic on the Network Access Client

Property	Values	Description
Source Port	Number or list item	The source port to which the client traffic classifier entry applies. You can type the port number, or select from the list of predefined application ports.

# 6

---

## Configuring Webtops

---

### Topics:

- *About webtops*
- *Configuring a webtop for network access*
- *Configuring a full webtop*
- *Webtop properties*

### About webtops

---

There are three webtop types you can define on Access Policy Manager®. You can define a network access only webtop, a portal access webtop, or a full webtop.

 **Important:** Do not assign a webtop for a portal access connection configured for minimal patching mode. This configuration does not work.

- A network access webtop provides a webtop for an access policy branch to which you assign only a network access resource.
- A portal access webtop provides a webtop for an access policy branch to which you assign only portal access resources.
- A full webtop provides an access policy ending for an access policy branch to which you can optionally assign portal access resources, app tunnels, remote desktops, and webtop links, in addition to a network access tunnel. The full webtop then provides your clients with a web page on which they can choose a network access connection to start.

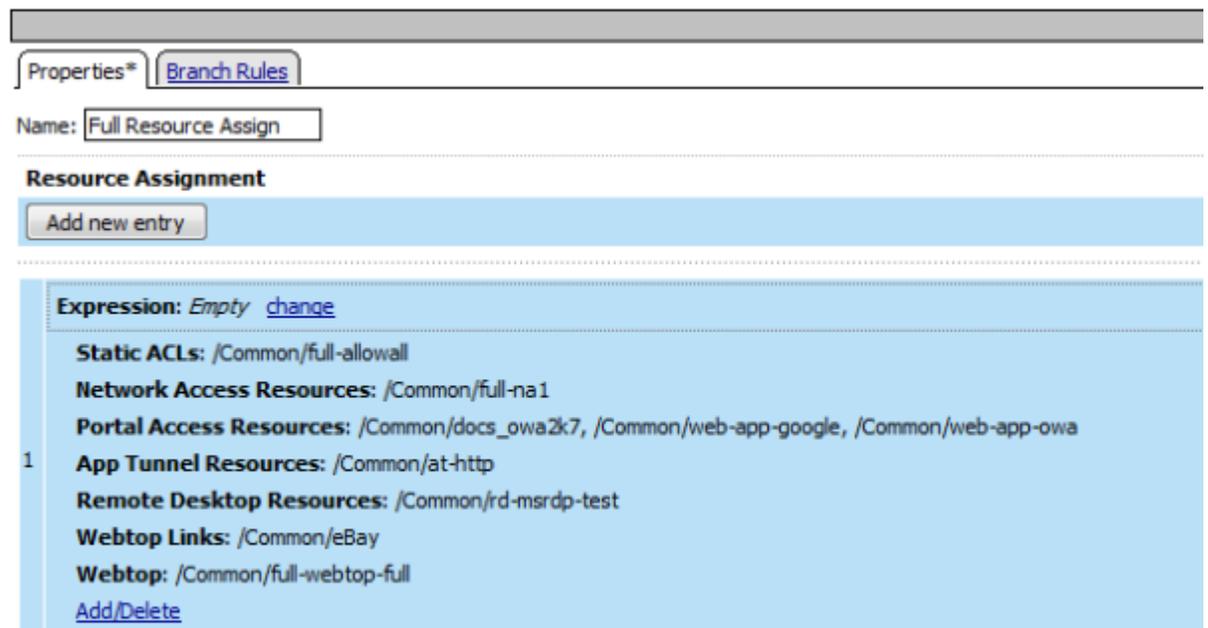

Figure 2: Resource assign action with resources and a webtop assigned

### Configuring a webtop for network access

---

A webtop allows your users to connect and disconnect from the network access connection.

1. On the Main tab, click **Access Policy > Access Profiles**.  
The Access Profiles List screen opens.

2. Click **Webtops**.
3. Click **Create** to create a new webtop.
4. Select the type of webtop to create.

Options	Description
<b>Network Access</b>	Select <b>Network Access</b> for a webtop to which you will assign only a single network access resource.
<b>Portal Access</b>	Select <b>Portal Access</b> for a webtop to which you assign only portal access resources.
<b>Full</b>	Select <b>Full</b> for a webtop to which you assign a single network access resource, multiple portal access resources, and multiple application access app tunnel resources, or any combination of the three types.

The webtop is now configured, and appears in the list. You can edit the webtop further, or assign it to an access policy.

To use this webtop, it must be assigned to an access policy with a full resource assign action or with a webtop and links assign action.

## Configuring a full webtop

---

A full webtop allows your users to connect and disconnect from a network access connection, portal access resources, app tunnels, remote desktops, and administrator-defined links.

1. On the Main tab, click **Access Policy > Webtops**.
2. Click **Create** to create a new webtop.
3. Type a name for the webtop you are creating.
4. From the **Type** list, select **Full**.
5. Click **Finished**.

The webtop is now configured, and appears in the list. You can edit the webtop further, or assign it to an access policy.

To use this webtop, it must be assigned to an access policy with a full resource assign action or with a webtop and links assign action. All resources assigned to the full webtop are displayed on the full webtop.

## Creating a webtop link

You can create and customize links that you can assign to full webtops. In this context, *links* are defined applications and websites that appear on a webtop, and can be clicked to open a web page or application. You can customize these links with descriptions and icons.

1. On the Main tab, click **Access Policy > Webtops > Webtop Links**.
2. Click **Create** to create a new webtop link.
3. In the **Name** field, type a name for the new webtop link.
4. In the **Application URI** field, type the application URI.
5. In the **Caption** field, type a descriptive caption.

The **Caption** field is pre-populated with the text from the **Name** field.

## Configuring Webtops

6. If you want to add a detailed description, type it in the **Detailed Description** field.
7. To specify an icon image for the item on the webtop, click in the **Image** field and choose an image, or click the **Browse** button.  
Click the **View/Hide** link to show or hide the currently selected image.
8. Click **Finished**.

The webtop link is now configured, and appears in the list, and on a full webtop assigned with the same action. You can edit the webtop link further, or assign it to an access policy.

Before you can use this webtop link, it must be assigned to an access policy with a full webtop, using either a full resource assign action or a webtop and links assign action.

### Customizing a webtop link

You can customize links that you assign to full webtops.

1. On the Main tab, click **Access Policy > Webtops > Webtop Links**.
2. Click the name of the webtop link you want to customize.  
The properties screen for the webtop link appears.
3. To change the description of the link, in the **Description** field, type a new description.
4. To change the URI of the link, in the **Application URI** field, type the application URI.
5. If you made changes on the properties screen, click **Update**.
6. Click the Customization tab.
7. Select the **Language** to customize, or click the **Create** button to create a new language customization.
8. If you clicked **Create** to create a new language customization, from the **Language** list, select the language to customize.
9. In the **Caption** field, type a descriptive caption.
10. In the **Detailed Description** field, type a detailed description.
11. In the **Image** field, click **Browse** to select an image to show on the webtop to represent the webtop link.  
Click the **View/Hide** link to show the currently assigned image.  
A webtop link image can be a GIF, BMP, JPG or PNG image up to 32 x 32 pixels in size.
12. Click **Finished**.

The webtop link is now configured, and appears in the list, and on a full webtop assigned with the same action. You can edit the webtop link further, or assign it to an access policy.

Before you can use this webtop link, it must be assigned to an access policy with a full webtop, using either a full resource assign action or a webtop and links assign action.

## Webtop properties

---

Use these properties to configure a webtop.

Property	Value	Description
Type	Network Access, Portal Access, or Full	<ul style="list-style-type: none"><li>• Use <b>Network Access</b> for a webtop to which you assign only a single network access resource.</li></ul>

<b>Property</b>	<b>Value</b>	<b>Description</b>
		<ul style="list-style-type: none"> <li>• Use <b>Portal Access</b> for a webtop to which you assign only portal access resources.</li> <li>• Use <b>Full</b> for a webtop to which you assign a single network access resource, multiple portal access resources, and multiple application access application tunnel resources, or any combination of the three types.</li> </ul>
<b>Portal Access Start URI</b>	URI	Specifies the URI that the web application starts. For <b>Full</b> webtops, portal access resources are published on the webtop with the associated URI you define when you select the <b>Publish on Webtop</b> option.
<b>Minimize to Tray</b>	Enabled or disabled	If this check box is selected, the webtop is minimized to the system tray automatically after the network access connection starts. With a network access webtop, the webtop automatically minimizes to the tray. With a full webtop, the webtop minimizes to the system tray only after the network access connection is started.

# Chapter

# 7

---

## Defining Connectivity Options

---

**Topics:**

- [About connectivity profiles](#)
  - [Creating a connectivity profile](#)
-

### About connectivity profiles

---

In the BIG-IP® Access Policy Manager®, a connectivity profile is the profile that you select in a virtual server definition to define connectivity and client settings for a network access session.

The connectivity profile contains:

- Network access connection compression settings
- Client settings for virtual servers and location awareness
- Client update settings
- Password caching settings
- Citrix® client settings
- Mobile client settings

### Creating a connectivity profile

---

You create a connectivity profile to configure client connections for a network access tunnel and clients.

1. On the Main tab, click **Access Policy > Secure Connectivity > Connectivity Profiles**.
2. Click **Create**.
3. Type a **Name** for the connectivity profile.
4. Select a **Parent Profile** for the connectivity profile, if required.
5. If you want to change network access compression settings, select the **Custom** check box, and configure the compression settings.
6. If you want to change application tunnel compression settings, select the **Custom** check box, and configure the compression settings.
7. Click **Finished**.

The connectivity profile appears in the list.

To provide functionality with a connectivity profile, you must add the connectivity profile and an access profile to a virtual server.

### About connectivity profile compression settings

Compression settings specify the available compression codecs for server-to-client connections. The server compares the available compression types configured in the connectivity profile with the available compression types on the client, and chooses the most effective mutual compression setting.

### Connectivity profile general settings

You can configure the following general settings in a connectivity profile.

Setting	Value	Description
Name		Specifies the name of the connectivity profile.

Setting	Value	Description
Parent Profile	A connectivity profile, selected from a list.	When you select a connectivity profile from the list and click <b>Update</b> , the current connectivity profile changes to match the settings configured in the parent profile.

### Connectivity profile network access compression settings

You can configure the following network access compression settings in a connectivity profile.

Setting	Value	Description
Compression Buffer Size	Number of bytes. The default is 4096.	Specifies the size of the output buffers containing compressed data.
gzip Compression Level	A preset, or a value between 1 and 9.	Specifies the degree to which the system compresses the content. Higher compression levels cause the compression process to be slower and the result to be more compressed. The default compression level is <b>6 - Optimal Compression</b> , which provides a balance between level of compression and CPU processing time. You can also select compression level <b>1 - Least Compression (Fastest)</b> , the lowest amount of compression, which requires the least processing time, or <b>9 - Most Compression (Slowest)</b> , the highest level of compression, which requires the most processing time. You can also select <b>Other</b> , then type a number between 1 and 9, or type 0 to disable compression.
gzip Memory Level	1-256 kb.	Specifies the number of kilobytes of memory that the system uses for internal compression buffers when compressing data. You can select a value between 1 and 256.
gzip Window Size	1-128 kb.	Specifies the number of kilobytes in the window size that the system uses when compressing data. You can select a value between 1 and 128.
CPU Saver	<b>Enabled</b> or <b>Disabled</b>	Specifies, when enabled, that the system monitors the percentage of CPU usage and adjusts compression rates automatically when the CPU usage reaches either the <b>CPU Saver High Threshold</b> or the <b>CPU Saver Low Threshold</b> .
CPU Saver High Threshold	Percentage	Specifies the percentage of CPU usage at which the system starts automatically decreasing the amount of content being compressed, as well as the amount of compression which the system is applying.
CPU Saver Low Threshold	Percentage	Specifies the percentage of CPU usage at which the system resumes content compression at the user-defined rates.

### Connectivity profile application tunnel compression settings

You can configure the following application tunnel compression settings in a connectivity profile.

## Defining Connectivity Options

Available Codec	Value	Description
LZO	<b>Enable</b> or <b>Disable</b>	Select the <b>LZO</b> check box to enable LZO compression. LZO compression offers a balance between CPU resources and compression ratio, compressing more than Deflate compression, but with less CPU resources than Bzip2.
Deflate	<b>Enable</b> or <b>Disable</b>	Select the <b>Deflate</b> check box to enable Deflate compression. Deflate compression uses the least CPU resources, but compresses the least effectively.
Bzip2	<b>Enable</b> or <b>Disable</b>	Select the <b>Bzip2</b> check box to enable Bzip2 compression. Bzip2 compression uses the most CPU resources, but compresses the most effectively.

## Creating an Access Policy for Network Access

---

**Topics:**

- *About access profiles*
  - *About access policies for network access*
-

### About access profiles

---

In the BIG-IP® Access Policy Manager®, an access profile is the profile that you select in a virtual server definition to establish a secured session. You can also configure an access profile to provide access control and security features to a local traffic virtual server hosting web applications.

The access profile contains:

- Access policy timeout and concurrent user settings
- Accepted language and default language settings
- Single Sign-On information and domain cookie information for the session
- Customization settings for the access profile
- The access policy for the profile

### About access policies for network access

---

Define an access policy for network access in order to provide access control conditions that you want users to satisfy, before they can connect to internal resources. For a network access policy, you need to configure a minimum of a resource assign action that assigns a network access resource.

### Creating an access profile

You create an access profile to provide the access policy configuration for a virtual server that establishes a secured session.

1. On the Main tab, click **Access Policy > Access Profiles**.  
The Access Profiles List screen opens.
2. Click **Create**.  
The New Profile screen opens.
3. Type a name for the access profile.
4. To configure timeout and session settings, select the **Custom** check box.
5. In the **Inactivity Timeout** field, type the number of seconds that should pass before the access policy times out. Type 0 to set no timeout.  
If there is no activity (defined by the **Session Update Threshold** and **Session Update Window** settings in the Network Access configuration) between the client and server within the specified threshold time, the system closes the current session.
6. In the **Access Policy Timeout** field, type the number of seconds that should pass before the access profile times out because of inactivity.  
Type 0 to set no timeout.  
You must select the associated **Custom** check box before you can configure this setting.
7. In the **Maximum Session Timeout** field, type the maximum number of seconds the session can exist.  
Type 0 to set no timeout.  
You must select the associated **Custom** check box before you can configure this setting.

8. In the **Max Concurrent Users** field, type the maximum number of users that can use this access profile at the same time.  
Type 0 to set no maximum.  
You must select the associated **Custom** check box before you can configure this setting.
9. In the **Max Sessions Per User** field, type the maximum number of concurrent sessions that one user can start.  
Type 0 to set no maximum.  
You must select the associated **Custom** check box before you can configure this setting.
10. In the **Max In Progress Sessions Per Client IP** field, type the maximum number of concurrent sessions that one client IP address can support.  
Type 0 to set no maximum.  
You must select the associated **Custom** check box before you can configure this setting.
11. Select the **Restrict to Single Client IP** check box to restrict the current session to a single IP address. This setting associates the session ID with the IP address.  
You must select the associated **Custom** check box before you can configure this setting.  
With this setting enabled, upon a request to the session, if the IP address has changed, the request is redirected to a logout page, the session ID is deleted, and a log entry is written to indicate that a session hijacking attempt was detected. If such a redirect is not possible, the request is denied and the same events occur.
12. To configure logout URIs, in the Configurations area, type each logout URI in the **URI** field, and then click **Add**.
13. In the **Logout URI Timeout** field, type the delay in seconds before logout occurs for the customized logout URIs defined in the **Logout URI Include** list.
14. In the SSO across Authentication Domains area, use the **Domain Mode** setting to select whether users log in to a single domain or multiple domains.
15. If you selected **Multiple Domains**, then in the **Primary Authentication URI** field, type the primary URI for authentication.
16. If the policy requires a secure cookie, in the **Cookie Options** area select the **Secure** check box to add the **secure** keyword to the session cookie. If you are configuring an LTM access scenario where you are using an HTTPS virtual server to authenticate the user, and then sending the user to an existing HTTP virtual server to use applications, clear this check box.
17. If the access policy requires a persistent cookie, in the **Cookie Options** area select the **Persistent** check box.  

This sets cookies if the session does not have a webtop. When the session is first established, session cookies are not marked as persistent, but when the first response is sent to the client after the access policy completes successfully, the cookies are marked persistent. Persistent cookies are updated for the expiration timeout every 60 seconds. The timeout is equal to session inactivity timeout. If the session inactivity timeout is overwritten in the access policy, the overwritten value will be used to set the persistent cookie expiration.
18. From the **SSO Configuration** list, select the SSO configuration.
19. In the **Domain Cookie** field, specify a domain cookie, if required.
20. In the Language Settings area, add and remove accepted languages, and set the default language.  

A browser uses the highest priority accepted language. If no browser language matches the accepted languages list, the browser uses the default language.
21. Click **Finished**.

The access profile appears in the Access Profiles List.

## Creating an Access Policy for Network Access

To provide functionality with an access profile, you must configure the access policy. The default access policy for a profile denies all traffic and contains no actions. Click **Edit** in the **Access Policy** column to edit the access policy.

### Access profile settings

You can configure the following settings in an access profile.

Setting	Value	Description and defaults
<b>Name</b>		Specifies the name of the access profile.
<b>Inactivity Timeout</b>	Number of seconds, or 0	Specifies the inactivity timeout for the connection. If there is no activity between the client and server within the specified threshold time, the system closes the current session. By default, the threshold is 0, which specifies that as long as a connection is established, the inactivity timeout is inactive. However, if an inactivity timeout value is set, when server traffic exceeds the specified threshold, the inactivity timeout is reset.
<b>Access Policy Timeout</b>	Number of seconds, or 0	Designed to keep malicious users from creating a denial-of-service (DoS) attack on your server. The timeout requires that a user, who has followed through on a redirect, must reach the webtop before the timeout expires. The default value is 300 seconds.
<b>Maximum Session Timeout</b>	Number of seconds, or 0	The maximum lifetime is from the time a session is created, to when the session terminates. By default, it is set to 0, which means no limit. When you configure a maximum session timeout setting other than 0, there is no way to extend the session lifetime, and the user must log out and then log back in to the server when the session expires.
<b>Max Concurrent Users</b>	Number of users, or 0	The number of sessions allowed at one time for this access profile. The default value is 0 which specifies unlimited sessions.
<b>Max Sessions Per User</b>	Number between 1 and 1000, or 0	Specifies the number of sessions for one user that can be active concurrently. The default value is 0, which specifies unlimited sessions. You can set a limit from 1-1000. Values higher than 1000 cause the access profile to fail.
<b>Logout URI Include</b>	One or more URIs	Specifies a list of URIs to include in the access profile to initiate session logout.
<b>Logout URI Timeout</b>	Logout delay URI in seconds	Specifies the time delay before the logout occurs, using the logout URIs defined in the logout URI include list.
<b>Domain Mode</b>	<b>Single Domain</b> or <b>Multiple Domains</b>	Select <b>Single Domain</b> to apply your SSO configuration to a single domain. Select <b>Multiple Domain</b> to apply your SSO configuration across multiple domains. This is useful in cases where you want to allow your users a single APM login session and apply it across multiple Local Traffic Manager™ or Access Policy Manager® virtual servers, front-ending different domains.   <b>Important:</b> All virtual servers must be on one single BIG-IP system in order to apply SSO configurations across multiple domains.

Setting	Value	Description and defaults
<b>Primary Authentication URI</b>	URI	The URI of your primary authentication server, for example <code>https://logon.siterequest.com</code> . This is required if you use SSO across multiple domains. You provide this URI so your users can access multiple back-end applications from multiple domains and hosts without requiring them to re-enter their credentials, because the user session is stored on the primary domain.
Cookie Options: <b>Secure</b>	Enable or disable check box	Enabled, this setting specifies to add the <b>secure</b> keyword to the session cookie. If you are configuring an application access control scenario where you are using an HTTPS virtual server to authenticate the user, and then sending the user to an existing HTTP virtual server to use applications, clear this check box.
Cookie Options: <b>Persistent</b>	Enable or disable check box	Enabled, this setting specifies to set cookies if the session does not have a webtop. When the session is first established, session cookies are not marked as persistent, but when the first response is sent to the client after the access policy completes successfully, the cookies are marked persistent.   <i>Note: Persistent cookies are updated for the expiration timeout every 60 seconds. The timeout is equal to the session inactivity timeout. If the session inactivity timeout is overwritten in the access policy, the overwritten value is used to set the persistent cookie expiration.</i>
<b>SSO Configuration</b>	Predefined SSO configuration	SSO configurations contain settings to configure single sign-on with an access profile. Select the SSO configuration from the list that you want applied to your domain.
<b>Domain Cookie</b>	A domain cookie	If you specify a domain cookie, then the line <code>domain=specified_domain</code> is added to the <code>MRHsession</code> cookie.
Configure Authentication Domains	Multiple	If you specify multiple domains, populate this area with hosts or domains. Each host or domain can have a separate SSO config, and you can set persistent or secure cookies. Click <b>Add</b> to add each host you configure.
<b>Accepted Languages</b>	Language strings	Adds a built-in or customized language to the list of accepted languages. Accepted languages can be customized separately and can present customized messages and screens to users, if the user's default browser language is one of the accepted languages. Select a language from the <b>Factory Builtin Languages</b> list and click the Move button (<<) to add it to the <b>Accepted Languages</b> list. Select a language from the <b>Additional Languages</b> list and click <b>Add</b> to add it to the <b>Accepted Languages</b> list.
<b>Factory Builtin Languages</b>	Languages in a predefined list	Lists the predefined languages on the Access Policy Manager system, which can be added to the <b>Accepted Languages</b> list. Predefined languages include customized messages and fields for common appearance items, as opposed to <b>Additional Languages</b> , which must be separately customized.
<b>Additional Languages</b>	Languages in a predefined list	Lists additional languages that can be added to the <b>Accepted Languages</b> list, and customized on the Access Policy Manager

## Creating an Access Policy for Network Access

Setting	Value	Description and defaults
		system. These languages are populated with English messages and fields and must be individually customized using the Customization menu, as opposed to <b>Factory Builtin Languages</b> , which are already customized.

### Adding network access to an access policy

Before you assign a network access resource to an access policy, you must:

- Create a network access resource
- Create an access profile
- Define a network access webtop or a full webtop

When you assign a network access resource to an access policy branch, a user who successfully completed the branch rule (which includes that access policy item) starts a network access tunnel.

1. On the Main tab, click **Access Policy > Access Profiles**.  
The Access Profiles List screen opens.
2. Click the name of the access profile for which you want to edit the access policy.  
The Access Profile properties screen opens for the profile you want to edit.
3. On the menu bar, click **Access Policy**.  
The Access Policy screen opens.
4. Click **Edit Access Policy for Profile *profile\_name***.  
The visual policy editor opens the access policy in a separate window or tab.
5. Click the [+] sign anywhere in your access profile to add your new policy action item.  
An Add Item window opens, listing Predefined Actions that are grouped by General Purpose, Authentication, and so on.
6. Select one of the following resource assignment actions and click **Add**.

Options	Description
<b>Resource Assign</b>	Select the <b>Resource Assign</b> action to add a network access resource only. <b>Resource Assign</b> does not allow you to add a webtop or ACLs. If you want to add ACLs, a webtop, or webtop links after you add a Resource Assign action, you can add them with the individual actions <b>ACL Assign</b> and <b>Webtop and Links Assign</b> .
<b>Full Resource Assign</b>	Select the <b>Full Resource Assign</b> action to add a network access resource, and optionally add a webtop, webtop links, and one or more ACLs.

7. Select the resource or resources to add.
  - If you added a **Full Resource Assign** action, on the Resource Assignment screen, click **Add New Entry**, then click **Add/Delete**, and select and add resources from the tabs, then click **Update**.
  - If you added a **Resource Assign** action, next to Network Access Resources, click **Add/Delete**.
8. Click **Save**.
9. Click **Apply Access Policy** to save your configuration.

A network access tunnel is assigned to the access policy. You may also assign a network access or full webtop. On the full webtop, users click the Network Access link to start the network access tunnel.

After you complete the access policy, you must define a connectivity profile. In the virtual server definition, you must select the access policy and connectivity profile.

## Configuring Virtual Servers for Network Access

---

### Topics:

- *Associating a virtual server with network access*
-

### Associating a virtual server with network access

---

When creating a virtual server for an access policy, specify that the virtual server is a host virtual server, and not a network virtual server.

1. On the Main tab, click **Local Traffic > Virtual Servers**.  
The Virtual Server List screen displays a list of existing virtual servers.
2. Click the name of the virtual server you want to modify.
3. For the **Destination** setting, select **Host** and in the **Address** field, type the IP address for the virtual server.
4. From the **HTTP Profile** list, select **http**.
5. In the Access Policy area, from the **Access Profile** list, select the access profile.
6. From the **Connectivity Profile** list, select the connectivity profile.
7. If you are creating a virtual server to use with portal access resources in addition to remote desktops, from the **Rewrite Profile** list, select the default **rewrite** profile, or another rewrite profile you created.
8. If you use server SSL for this connection, from the **SSL Profile (Server)** list, select a server SSL profile.
9. If you use client SSL for this profile, from the **SSL Profile (Client)** list, select a client SSL profile.
10. If you want to provide connections to Citrix desktop resources or Java RDP clients for Application Access, or allow Java rewriting for Portal Access, select the **Citrix & Java Support** check box.  
You must enable this setting to make socket connections from a patched Java applet. If your applet doesn't require socket connections, or only uses HTTP to request resources, this setting is not required.
11. If you want to provide native integration with an OAM server for authentication and authorization, select the **OAM Support** check box.  
You must have an OAM server configured in order to enable OAM support.
12. Click **Update**.

Your access policy is now associated with the virtual server.
